

A brief description (1-2 paragraphs) of your application: which dataset do you plan to use, who are the users of the application, who are the administrators of the database systems etc, what functionalities you may like to support.

We want to create a course planner application for University of Waterloo Computer Science students. Our users will be University of Waterloo Computer Science students eligible for the 2023-2024 year checklist. We want to support enabling students to complete their checklist, mark courses as complete, and explore available anti-requisites based on completed courses, as well as prerequisites and co-requisites for desired courses.

We plan to use the Waterloo course dataset, owned by the University of Waterloo. We plan to store a course table (course metadata), user table (user metadata), user checklist table (selected courses, completion status), and a course relationship table (anti-requisite, prerequisite, co-requisite information). Richard Bai will be the database administrator.

A brief description (1-2 paragraphs) of your choice of platform (school servers, local machines) and user interface (e.g., how will users interact with your application? command line or web or GUI, etc?)

We will use our local machines to initialize backend servers, a remote database to store our data (e.g., Supabase), and a web app for users to interact with our application: edit checklists, select courses, check antirequisites, etc.

A section on members, that lists the members of your team, and for each member, a description of effort and progress made by this member to date.

A link to the GitHub repo you will use throughout the project to store your source code. We recommend having 4 directories at the top: milestone-0, milestone-1, milestone-2, milestone-3.
